Description**FIELD**

5 [0001] The present disclosure relates to quantization of the gain of a fixed contribution of an excitation in a coded sound signal. The present disclosure also relates to joint quantization of the gains of the adaptive and fixed contributions of the excitation.

BACKGROUND

10 [0002] In a coder of a codec structure, for example a CELP (Code-Excited Linear Prediction) codec structure such as ACELP (Algebraic Code-Excited Linear Prediction), an input speech or audio signal (sound signal) is processed in short segments, called frames. In order to capture rapidly varying properties of an input sound signal, each frame is further divided into sub-frames. A CELP codec structure also produces adaptive codebook and fixed codebook contributions of an excitation that are added together to form a total excitation. Gains related to the adaptive and fixed codebook contributions of the excitation are quantized and transmitted to a decoder along with other encoding parameters. The adaptive codebook contribution and the fixed codebook contribution of the excitation will be referred to as "the adaptive contribution" and "the fixed contribution" of the excitation throughout the document. US 7,191,122 B1 discloses a speech compression system and method.

20 [0003] There is a need for a technique for quantizing the gains of the adaptive and fixed excitation contributions that improve the robustness of the codec against frame erasures or packet losses that can occur during transmission of the encoding parameters from the coder to the decoder.

SUMMARY

25 [0004] According to a first aspect, the present disclosure relates to a device for quantizing a gain of a fixed contribution of an excitation in a frame, as set forth in claim 1.

[0005] The present disclosure also relates to a method for quantizing a gain of a fixed contribution of an excitation in a frame, as set forth in claim 12.

30 [0006] According to a third aspect, there is provided a device for jointly quantizing gains of adaptive and fixed contributions of an excitation in a frame of a coded sound signal, as set forth in claim 4.

[0007] The present disclosure further relates to a method for jointly quantizing gains of adaptive and fixed contributions of an excitation in a frame of a coded sound signal, as set forth in claim 15.

35 [0008] According to a fifth aspect, there is provided a device for retrieving a quantized gain of a fixed contribution of an excitation in a sub-frame of a frame, as set forth in claim 9.

[0009] The present disclosure is also concerned with a method for retrieving a quantized gain of a fixed contribution of an excitation in a sub-frame of a frame, as set forth in claim 18.

[0010] The present disclosure is still further concerned with a device for retrieving quantized gains of adaptive and fixed contributions of an excitation in a sub-frame of a frame, as set forth in claim 10.

40 [0011] According to a further aspect, the disclosure describes a method for retrieving quantized gains of adaptive and fixed contributions of an excitation in a sub-frame of a frame, as set forth in claim 20. Preferred embodiments are set forth in the dependent claims.

[0012] The foregoing and other features will become more apparent upon reading of the following non-restrictive description of illustrative embodiments, given by way of example only with reference to the accompanying drawings.

45

BRIEF DESCRIPTION OF THE DRAWINGS

[0013] In the appended drawings:

50 Figure 1 is a schematic diagram describing the construction of a filtered excitation in a CELP-based coder;

Figure 2 is a schematic block diagram describing an estimator of the gain of the fixed contribution of the excitation in a first sub-frame of each frame;

55 Figure 3 is a schematic block diagram describing an estimator of the gain of the fixed contribution of the excitation in all sub-frames following the first sub-frame;

Figure 4 is a schematic block diagram describing a state machine in which estimation coefficients are calculated

and used for designing a gain codebook for each sub-frame;

Figure 5 is a schematic block diagram describing a gain quantizer; and

5 Figure 6 is a schematic block diagram of another embodiment of gain quantizer equivalent to the gain quantizer of Figure 5.

DETAILED DESCRIPTION

10 **[0014]** In the following, there is described quantization of a gain of a fixed contribution of an excitation in a coded sound signal, as well as joint quantization of gains of adaptive and fixed contributions of the excitation. The quantization can be applied to any number of sub-frames and deployed with any input speech or audio signal (input sound signal) sampled at any arbitrary sampling frequency. Also, the gains of the adaptive and fixed contributions of the excitation are quantized without the need of inter-frame prediction. The absence of inter-frame prediction results in improvement of the robustness against frame erasures or packet losses that can occur during transmission of encoded parameters.

15 **[0015]** The gain of the adaptive contribution of the excitation is quantized directly whereas the gain of the fixed contribution of the excitation is quantized through an estimated gain. The estimation of the gain of the fixed contribution of the excitation is based on parameters that exist both at the coder and the decoder. These parameters are calculated during processing of the current frame. Thus, no information from a previous frame is required in the course of quantization or decoding which, as mentioned hereinabove, improves the robustness of the codec against frame erasures.

20 **[0016]** Although the following description will refer to a CELP (Code-Excited Linear Prediction) codec structure, for example ACELP (Algebraic Code-Excited Linear Prediction), it should be kept in mind that the subject matter of the present disclosure may be applied to other types of codec structures.

25 ***Optimal unquantized gains for the adaptive and fixed contributions of the excitation***

[0017] In the art of CELP coding, the excitation is composed of two contributions: the adaptive contribution (adaptive codebook excitation) and the fixed contribution (fixed codebook excitation). The adaptive codebook is based on long-term prediction and is therefore related to the past excitation. The adaptive contribution of the excitation is found by means of a closed-loop search around an estimated value of a pitch lag. The estimated pitch lag is found by means of a correlation analysis. The closed-loop search consists of minimizing the mean square weighted error (MSWE) between a target signal (in CELP coding, a perceptually filtered version of the input speech or audio signal (input sound signal)) and the filtered adaptive contribution of the excitation scaled by an adaptive codebook gain. The filter in the closed-loop search corresponds to the weighted synthesis filter known in the art of CELP coding. A fixed codebook search is also carried out by minimizing the mean squared error (MSE) between an updated target signal (after removing the adaptive contribution of the excitation) and the filtered fixed contribution of the excitation scaled by a fixed codebook gain. The construction of the total filtered excitation is shown in Figure 1. For further reference, an implementation of CELP coding is described in the following document: 3GPP TS 26.190, "Adaptive Multi-Rate - Wideband (AMR-WB) speech codec; Transcoding functions".

30 **[0018]** Figure 1 is a schematic diagram describing the construction of the filtered total excitation in a CELP coder. The input signal 101, formed by the above mentioned target signal, is denoted as $x(i)$ and is used as a reference during the search of gains for the adaptive and fixed contributions of the excitation. The filtered adaptive contribution of the excitation is denoted as $y(i)$ and the filtered fixed contribution of the excitation (innovation) is denoted as $z(i)$. The corresponding gains are denoted as g_p for the adaptive contribution and g_c for the fixed contribution of the excitation. As illustrated in Figure 1, an amplifier 104 applies the gain g_p to the filtered adaptive contribution $y(i)$ of the excitation and an amplifier 105 applies the gain g_c to the filtered fixed contribution $z(i)$ of the excitation. The optimal quantized gains are found by means of minimization of the mean square of the error signal $e(i)$ calculated through a first subtractor 107 subtracting the signal $g_p y(i)$ at the output of the amplifier 104 from the target signal x_i and a second subtractor 108 subtracting the signal $g_c z(i)$ at the output of the amplifier 105 from the result of the subtraction from the subtractor 107. For all signals in Figure 1, the index i denotes the different signal samples and runs from 0 to $L-1$, where L is the length of each sub-frame. As well known to people skilled in the art, the filtered adaptive codebook contribution is usually computed as the convolution between the adaptive codebook excitation vector $v(n)$ and the impulse response of the weighted synthesis filter $h(n)$, that is $y(n) = v(n) * h(n)$. Similarly, the filtered fixed codebook excitation $z(n)$ is given by $z(n) = c(n) * h(n)$, where $c(n)$ is the fixed codebook excitation.

35 **[0019]** Assuming the knowledge of the target signal $x(i)$, the filtered adaptive contribution of the excitation $y(i)$ and the filtered fixed contribution of the excitation $z(i)$, the optimal set of unquantized gains g_p and g_c is found by minimizing the energy of the error signal $e(i)$ given by the following relation:

$$e(i) = x(i) - g_p y(i) - g_c z(i), \quad i = 0, \dots, L-1 \quad (1)$$

[0020] Equation (1) can be given in vector form as

$$\mathbf{e} = \mathbf{x} - g_p \mathbf{y} - g_c \mathbf{z} \quad (2)$$

$$\mathbf{e}^t \mathbf{e} = \sum_{i=0}^{L-1} e^2(i),$$

and minimizing the energy of the error signal, where t denotes vector transpose, results in optimum unquantized gains

$$g_{p,opt} = \frac{c_1 c_2 - c_3 c_4}{c_0 c_2 - c_4^2}, \quad g_{c,opt} = \frac{c_0 c_3 - c_1 c_4}{c_0 c_2 - c_4^2} \quad (3)$$

where the constants or correlations c_0, c_1, c_2, c_3, c_4 and c_5 are calculated as

$$c_0 = \mathbf{y}^t \mathbf{y}, \quad c_1 = \mathbf{x}^t \mathbf{y}, \quad c_2 = \mathbf{z}^t \mathbf{z}, \quad c_3 = \mathbf{x}^t \mathbf{z}, \quad c_4 = \mathbf{y}^t \mathbf{z}, \quad c_5 = \mathbf{x}^t \mathbf{x}. \quad (4)$$

[0021] The optimum gains in Equation (3) are not quantized directly, but they are used in training a gain codebook as will be described later. The gains are quantized jointly, after applying prediction to the gain of the fixed contribution of the excitation. The prediction is performed by computing an estimated value of the gain g_{c0} of the fixed contribution of the excitation. The gain of the fixed contribution of the excitation is given by $g_c = g_{c0} \gamma$ where γ is a correction factor. Therefore, each codebook entry contains two values. The first value corresponds to the quantized gain g_p of the adaptive contribution of the excitation. The second value corresponds to the correction factor γ which is used to multiply the estimated gain g_{c0} of the fixed contribution of the excitation. The optimum index in the gain codebook (g_p and γ) is found by minimizing the mean squared error between the target signal and filtered total excitation. Estimation of the gain of the fixed contribution of the excitation is described in detail below.

Estimation of the gain of the fixed contribution of the excitation

[0022] Each frame contains a certain number of sub-frames. Let us denote the number of sub-frames in a frame as K and the index of the current sub-frame as k . The estimation g_{c0} of the gain of the fixed contribution of the excitation is performed differently in each sub-frame.

[0023] Figure 2 is a schematic block diagram describing an estimator 200 of the gain of the fixed contribution of the excitation (hereinafter fixed codebook gain) in a first sub-frame of each frame.

[0024] The estimator 200 first calculates an estimation of the fixed codebook gain in response to a parameter t representative of the classification of the current frame. The energy of the innovation codevector from the fixed codebook is then subtracted from the estimated fixed codebook gain to take into consideration this energy of the filtered innovation codevector. The resulting, estimated fixed codebook gain is multiplied by a correction factor selected from a gain codebook to produce the quantized fixed codebook gain g_c .

[0025] In one embodiment, the estimator 200 comprises a calculator 201 of a linear estimation of the fixed codebook gain in logarithmic domain. The fixed codebook gain is estimated assuming unity-energy of the innovation codevector 202 from the fixed codebook. Only one estimation parameter is used by the calculator 201, the parameter t representative of the classification of the current frame. A subtractor 203 then subtracts the energy of the filtered innovation codevector 202 from the fixed codebook in logarithmic domain from the linear estimated fixed codebook gain in logarithmic domain at the output of the calculator 201. A converter 204 converts the estimated fixed codebook gain in logarithmic domain from the subtractor 203 to linear domain. The output in linear domain from the converter 204 is the estimated fixed codebook gain g_{c0} . A multiplier 205 multiplies the estimated gain g_{c0} by the correction factor 206 selected from the gain codebook. As described in the preceding paragraph, the output of the multiplier 205 constitutes the quantized fixed codebook gain g_c .

[0026] The quantized gain g_p of the adaptive contribution of the excitation (hereinafter the adaptive codebook gain) is selected directly from the gain codebook. A multiplier 207 multiplies the filtered adaptive excitation 208 from the

adaptive codebook by the quantized adaptive codebook gain g_p to produce the filtered adaptive contribution 209 of the filtered excitation. Another multiplier 210 multiplies the filtered innovation codevector 202 from the fixed codebook by the quantized fixed codebook gain g_c to produce the filtered fixed contribution 211 of the filtered excitation. Finally, an adder 212 sums the filtered adaptive 209 and fixed 211 contributions of the excitation to form the total filtered excitation 214.

[0027] In the first sub-frame of the current frame, the estimated fixed codebook gain in logarithmic domain at the output of the subtractor 203 is given by

$$G_{c0}^{(1)} = a_0 + a_1 t - \log_{10}(\sqrt{E_i}) \quad (5)$$

where $G_{c0}^{(1)} = \log_{10}(g_{c0}^{(1)})$.

[0028] The inner term inside the logarithm of Equation (5) corresponds to the square root of the energy of the filtered innovation vector 202 (E_i is the energy of the filtered innovation vector in the first sub-frame of frame n). This inner term (square root of the energy E_i) is determined by a first calculator 215 of the energy E_i of the filtered innovation vector 202 and a calculator 216 of the square root of that energy E_i . A calculator 217 then computes the logarithm of the square root of the energy E_i for application to the negative input of the subtractor 203. The inner term (square root of the energy E_i) has non-zero energy; the energy is incremented by a small amount in case of all-zero frames to avoid $\log(0)$.

[0029] The estimation of the fixed codebook gain in calculator 201 is linear in logarithmic domain with estimation coefficients a_0 and a_1 which are found for each sub-frame by means of a mean square minimization on a large signal database (training) as will be explained in the following description. The only estimation parameter in the equation, t , denotes the classification parameter for frame n (in one embodiment, this value is constant for all sub-frames in frame n). Details about classification of the frames are given below. Finally, the estimated value of the gain in logarithmic

domain is converted back to the linear domain ($g_{c0}^{(1)} = 10^{G_{c0}^{(1)}}$) by the calculator 204 and used in the search process for the best index of the gain codebook as will be explained in the following description.

[0030] The superscript ⁽¹⁾ denotes the first sub-frame of the current frame n .

[0031] As explained in the foregoing description, the parameter t representative of the classification of the current frame is used in the calculation of the estimated fixed codebook gain g_{c0} . Different codebooks can be designed for different classes of voice signals. However, this will increase memory requirements. Also, estimation of the fixed codebook gain in the frames following the first frame can be based on the frame classification parameter t and the available adaptive and fixed codebook gains from previous sub-frames in the current frame. The estimation is confined to the frame boundary to increase robustness against frame erasures.

[0032] For example, frames can be classified as unvoiced, voiced, generic, or transition frames. Different alternatives can be used for classification. An example is given later below as a non-limitative illustrative embodiment. Further, the number of voice classes can be different from the one used hereinabove. For example the classification can be only voiced or unvoiced in one embodiment. In another embodiment more classes can be added such as strongly voiced and strongly unvoiced.

[0033] The values for the classification estimation parameter t can be chosen arbitrarily. For example, for narrowband signals, the values of parameter t are set to: 1, 3, 5, and 7, for unvoiced, voiced, generic, and transition frames, respectively, and for wideband signals, they are set to 0, 2, 4, and 6, respectively. However, other values for the estimation parameter t can be used for each class. Including this estimation, classification parameter t in the design and training for determining estimation parameters will result in better estimation g_{c0} of the fixed codebook gain.

[0034] The sub-frames following the first sub-frame in a frame use slightly different estimation scheme. The difference is in fact that in these sub-frames, both the quantized adaptive codebook gain and the quantized fixed codebook gain from the previous sub-frame(s) in the current frame are used as auxiliary estimation parameters to increase the efficiency.

[0035] Figure 3 is a schematic block diagram of an estimator 300 for estimating the fixed codebook gain in the sub-frames following the first sub-frame in a current frame. The estimation parameters include the classification parameter t and the quantized values (parameters 301) of both the adaptive and fixed codebook gains from previous sub-frames of the current frame. These parameters 301 are denoted as $g_p^{(1)}$, $g_c^{(1)}$, $g_p^{(2)}$, $g_c^{(2)}$, etc. where the superscript refers to first, second and other previous sub-frames. An estimation of the fixed codebook gain is calculated and is multiplied by a correction factor selected from the gain codebook to produce a quantized fixed codebook gain g_c , forming the gain of the fixed contribution of the excitation (this estimated fixed codebook gain is different from that of the first sub-frame).

[0036] In one embodiment, a calculator 302 computes a linear estimation of the fixed codebook gain again in logarithmic domain and a converter 303 converts the gain estimation back to linear domain. The quantized adaptive codebook gains

$g_p^{(1)}, g_p^{(2)}$, etc. from the previous sub-frames are supplied to the calculator 302 directly while the quantized fixed codebook gains $g_c^{(1)}, g_c^{(2)}$, etc. from the previous sub-frames are supplied to the calculator 302 in logarithmic domain through a logarithm calculator 304. A multiplier 305 then multiplies the estimated fixed codebook gain g_{c0} (which is different from that of the first sub-frame) from the converter 303 by the correction factor 306, selected from the gain codebook. As described in the preceding paragraph, the multiplier 305 then outputs a quantized fixed codebook gain g_c , forming the gain of the fixed contribution of the excitation.

[0037] A first multiplier 307 multiplies the filtered adaptive excitation 308 from the adaptive codebook by the quantized adaptive codebook gain g_p selected directly from the gain codebook to produce the adaptive contribution 309 of the excitation. A second multiplier 310 multiplies the filtered innovation codevector 311 from the fixed codebook by the quantized fixed codebook gain g_c to produce the fixed contribution 312 of the excitation. An adder 313 sums the filtered adaptive 309 and filtered fixed 312 contributions of the excitation together so as to form the total filtered excitation 314 for the current frame.

[0038] The estimated fixed codebook gain from the calculator 302 in the k^{th} sub-frame of the current frame in logarithmic domain is given by

$$G_{c0}^{(k)} = a_0 + a_1 t + \sum_{j=1}^{k-1} (b_{2j-2} G_c^{(j)} + b_{2j-1} g_p^{(j)}), \quad k = 2, \dots, K. \quad (6)$$

where $G_c^{(k)} = \log_{10}(g_c^{(k)})$ is the quantized fixed codebook gain in logarithmic domain in sub-frame k , and $g_p^{(k)}$ is the quantized adaptive codebook gain in sub-frame k .

[0039] For example, in one embodiment, four (4) sub-frames are used ($K=4$) so the estimated fixed codebook gains, in logarithmic domain, in the second, third, and fourth sub-frames from the calculator 302 are given by the following relations:

$$G_{c0}^{(2)} = a_0 + a_1 t + b_0 G_c^{(1)} + b_1 g_p^{(1)},$$

$$G_{c0}^{(3)} = a_0 + a_1 t + b_0 G_c^{(1)} + b_1 g_p^{(1)} + b_2 G_c^{(2)} + b_3 g_p^{(2)},$$

and

$$G_{c0}^{(4)} = a_0 + a_1 t + b_0 G_c^{(1)} + b_1 g_p^{(1)} + b_2 G_c^{(2)} + b_3 g_p^{(2)} + b_4 G_c^{(3)} + b_5 g_p^{(3)}.$$

[0040] The above estimation of the fixed codebook gain is based on both the quantized adaptive and fixed codebook gains of all previous sub-frames of the current frame. There is also another difference between this estimation scheme and the one used in the first sub-frame. The energy of the filtered innovation vector from the fixed codebook is not subtracted from the linear estimation of the fixed codebook gain in the logarithmic domain from the calculator 302. The reason comes from the use of the quantized adaptive codebook and fixed codebook gains from the previous sub-frames in the estimation equation. In the first sub-frame, the linear estimation is performed by the calculator 201 assuming unit energy of the innovation vector. Subsequently, this energy is subtracted to bring the estimated fixed codebook gain to the same energetic level as its optimal value (or at least close to it). In the second and subsequent sub-frames, the previous quantized values of the fixed codebook gain are already at this level so there is no need to take the energy of the filtered innovation vector into consideration. The estimation coefficients a_j and b_j are different for each sub-frame and they are determined offline using a large training database as will be described later below.

Calculation of estimation coefficients

[0041] An optimal set of estimation coefficients is found on a large database containing clean, noisy and mixed speech signals in various languages and levels and with male and female talkers.

[0042] The estimation coefficients are calculated by running the codec with optimal unquantized values of adaptive and fixed codebook gains on the large database. It is reminded that the optimal unquantized adaptive and fixed codebook gains are found according to Equations (3) and (4).

[0043] In the following description it is assumed that the database comprises $N+1$ frames, and the frame index is $n =$

0, ..., N. The frame index n is added to the parameters used in the training which vary on a frame basis (classification, first sub-frame innovation energy, and optimum adaptive and fixed codebook gains).

[0044] The estimation coefficients are found by minimizing the mean square error between the estimated fixed codebook gain and the optimum gain in the logarithmic domain over all frames in the database.

[0045] For the first sub-frame, the mean square error energy is given by

$$E_{est}^{(1)} = \sum_{n=0}^N \left[G_{c0}^{(1)}(n) - \log_{10} \left(g_{c,opt}^{(1)}(n) \right) \right]^2 \quad (7)$$

[0046] From Equation (5), the estimated fixed codebook gain in the first sub-frame of frame n is given by

$$G_{c0}^{(1)}(n) = a_0 + a_1 t(n) - \log_{10}(\sqrt{E_i(n)}),$$

then the mean square error energy is given by

$$E_{est}^{(1)} = \sum_{n=0}^N \left[a_0 + a_1 t(n) - \log_{10}(\sqrt{E_i^{(1)}(n)}) - \log_{10}(g_{c,opt}^{(1)}(n)) \right]^2. \quad (8)$$

[0047] In above equation above (8), E_{est} is the total energy (on the whole database) of the error between the estimated and optimal fixed codebook gains, both in logarithmic domain. The optimal, fixed codebook gain in the first sub-frame is denoted $g_{c,opt}^{(1)}$. As mentioned in the foregoing description, $E_i(n)$ is the energy of the filtered innovation vector from the fixed codebook and $t(n)$ is the classification parameter of frame n . The upper index (1) is used to denote the first sub-frame and n is the frame index.

[0048] The minimization problem may be simplified by defining a normalized gain of the innovation vector in logarithmic domain. That is

$$G_i^{(1)}(n) = \log_{10}(\sqrt{E_i^{(1)}(n)}) + \log_{10}(g_{c,opt}^{(1)}(n)), \quad n = 0, \dots, N-1. \quad (9)$$

[0049] The total error energy then becomes

$$E_{est}^{(1)} = \sum_{n=0}^N \left[a_0 + a_1 t(n) - G_i^{(1)}(n) \right]^2. \quad (10)$$

[0050] The solution of the above defined MSE (Mean Square Error) problem is found by the following pair of partial derivatives

$$\frac{\partial}{\partial a_0} E_{est}^{(1)} = 0, \quad \frac{\partial}{\partial a_1} E_{est}^{(1)} = 0.$$

[0051] The optimal values of estimation coefficients resulting from the above equations are given by

$$a_0 = \frac{\sum_{n=0}^N t^2(n) \sum_{n=0}^N G_i^{(1)}(n) - \sum_{n=0}^N t(n) \sum_{n=0}^N t(n) G_i^{(1)}(n)}{N \sum_{n=0}^N t^2(n) + \left[\sum_{n=0}^N t(n) \right]^2}, \quad (11)$$

$$a_1 = \frac{N \sum_{n=0}^N t(n) G_i^{(1)}(n) - \sum_{n=0}^N t(n) \sum_{n=0}^N G_i^{(1)}(n)}{N \sum_{n=0}^N t^2(n) + \left[\sum_{n=0}^N t(n) \right]^2}.$$

[0052] Estimation of the fixed codebook gain in the first sub-frame is performed in logarithmic domain and the estimated fixed codebook gain should be as close as possible to the normalized gain of the innovation vector in logarithmic domain, $G_i^{(1)}(n)$.

[0053] For the second and other subsequent sub-frames, the estimation scheme is slightly different. The error energy is given by

$$E_{est}^{(k)} = \sum_{n=0}^N \left[G_{c0}^{(k)}(n) - G_{c,opt}^{(k)}(n) \right]^2, \quad k = 2, \dots, K. \quad (12)$$

where $G_{c,opt}^{(k)} = \log_{10}(g_{c,opt}^{(k)})$. Substituting Equation (6) into Equation (12) the following is obtained

$$E_{est}^{(k)} = \sum_{n=0}^N \left[a_0 + a_1 t(n) + \sum_{j=1}^{k-1} \left(b_{2j-2} G_c^{(j)}(n) + b_{2j-1} g_p^{(j)}(n) \right) - G_{c,opt}^{(k)}(n) \right]^2 \quad (13)$$

[0054] For the calculation of the estimation coefficients in the second and subsequent sub-frames of each frame, the quantized values of both the fixed and adaptive codebook gains of previous sub-frames are used in the above Equation (13). Although it is possible to use the optimal unquantized gains in their place, the usage of quantized values leads to the maximum estimation efficiency in all sub-frames and consequently to better overall performance of the gain quantizer.

[0055] Thus, the number of estimation coefficients increases as the index of the current sub-frame is advanced. The gain quantization itself is described in the following description. The estimation coefficients a_i and b_i are different for each sub-frame, but the same symbols were used for the sake of simplicity. Normally, they would either have the superscript (k) associated therewith or they would be denoted differently for each sub-frame, wherein k is the sub-frame index.

[0056] The minimization of the error function in Equation (13) leads to the following system of linear equations

[0062] Referring to Figure 5, the two-entry gain codebook 503 is searched and each index provides two values - the adaptive codebook gain g_p and the correction factor γ . A multiplier 504 multiplies the correction factor γ by the estimated fixed codebook gain g_{c0} and the resulting value is used as the quantized gain 505 of the fixed contribution of the excitation (quantized fixed codebook gain). Another multiplier 506 multiplies the filtered adaptive excitation 505 from the adaptive codebook by the quantized adaptive codebook gain g_p from the gain codebook 503 to produce the adaptive contribution 507 of the excitation. A multiplier 508 multiplies the filtered innovation codevector 502 by the quantized fixed codebook gain 505 to produce the fixed contribution 509 of the excitation. An adder 510 sums both the adaptive 507 and fixed 509 contributions of the excitation together so as to form the filtered total excitation 511. A subtractor 512 subtracts the filtered total excitation 511 from the target signal x_i to produce the error signal e_i . A calculator 513 computes the energy 515 of the error signal e_i and supplies it back to the gain codebook searching mechanism. All or a subset of the indices of the gain codebook 501 are searched in this manner and the index of the gain codebook 503 yielding the lowest error energy 515 is selected as the winning index and sent to the decoder.

[0063] The gain quantization can be performed by minimizing the energy of the error in Equation (2). The energy is given by

$$E = \mathbf{e}'\mathbf{e} = (\mathbf{x} - g_p\mathbf{y} - g_c\mathbf{z})'(\mathbf{x} - g_p\mathbf{y} - g_c\mathbf{z}). \quad (15)$$

[0064] Substituting g_c by γg_{c0} the following relation is obtained

$$E = c_5 + g_p^2 c_0 - 2g_p c_1 + \gamma^2 g_{c0}^2 c_2 - 2\gamma g_{c0} c_3 + 2g_p \gamma g_{c0} c_4 \quad (16)$$

where the constants or correlations c_0, c_1, c_2, c_3, c_4 and c_5 are calculated as in Equation (4) above. The constants or correlations c_0, c_1, c_2, c_3, c_4 and c_5 , and the estimated gain g_{c0} are computed before the search of the gain codebook 503, and then the energy in Equation (16) is calculated for each codebook index (each set of entry values g_p and γ).

[0065] The codevector from the gain codebook 503 leading to the lowest energy 515 of the error signal e_i is chosen as the winning codevector and its entry values correspond to the quantized values g_p and γ . The quantized value of the fixed codebook gain is then calculated as

$$g_c = g_{c0} \cdot \gamma.$$

[0066] Figure 6 is a schematic block diagram of an equivalent gain quantizer 600 as in Figure 5, performing calculation of the energy E_i of the error signal e_i using Equation (16). More specifically, the gain quantizer 600 comprises a gain codebook 601, a calculator 602 of constants or correlations, and a calculator 603 of the energy 604 of the error signal. The calculator 602 calculates the constants or correlations c_0, c_1, c_2, c_3, c_4 and c_5 using Equation (4) and the target vector \mathbf{x} , the filtered adaptive excitation vector \mathbf{y} from the adaptive codebook, and the filtered fixed codevector \mathbf{z} from the fixed codebook, wherein t denotes vector transpose. The calculator 603 uses Equation (16) to calculate the energy E_i of the error signal e_i from the estimated fixed codebook gain g_{c0} , the correlations c_0, c_1, c_2, c_3, c_4 and c_5 from calculator 602, and the quantized adaptive codebook gain g_p and the correction factor γ from the gain codebook 601. The energy 604 of the error signal from the calculator 603 is supplied back to the gain codebook searching mechanism. Again, all or a subset of the indices of the gain codebook 601 are searched in this manner and the index of the gain codebook 601 yielding the lowest error energy 604 is selected as the winning index and sent to the decoder.

[0067] In the gain quantizer 600 of Figure 6, the gain codebook 601 has a size that can be different depending on the sub-frame. Better estimation of the fixed codebook gain is attained in later sub-frames in a frame due to increased number of estimation parameters. Therefore a smaller number of bits can be used in later sub-frames. In one embodiment, four (4) sub-frames are used where the numbers of bits for the gain codebook are 8, 7, 6, and 6 corresponding to sub-frames 1, 2, 3, and 4, respectively. In another embodiment at a lower bit rate, 6 bits are used in each sub-frame.

[0068] In the decoder, the received index is used to retrieve the values of quantized adaptive codebook gain g_p and correction factor γ from the gain codebook. The estimation of the fixed codebook gain is performed in the same manner as in the coder, as described in the foregoing description. The quantized value of the fixed codebook gain is calculated by the equation $g_c = g_{c0} \cdot \gamma$. Both the adaptive codevector and the innovation codevector are decoded from the bitstream and they become adaptive and fixed excitation contributions that are multiplied by the respective adaptive and fixed codebook gains. Both excitation contributions are added together to form the total excitation. The synthesis signal is found by filtering the total excitation through a LP synthesis filter as known in the art of CELP coding.

Signal classification

[0069] Different methods can be used for determining classification of a frame, for example parameter t of Figure 1. A non-limitative example is given in the following description where frames are classified as unvoiced, voiced, generic, or transition frames. However, the number of voice classes can be different from the one used in this example. For example the classification can be only voiced or unvoiced in one embodiment. In another embodiment more classes can be added such as strongly voiced and strongly unvoiced.

[0070] Signal classification can be performed in three steps, where each step discriminates a specific signal class. First, a signal activity detector (SAD) discriminates between active and inactive speech frames. If an inactive speech frame is detected (background noise signal) then the classification chain ends and the frame is encoded with comfort noise generation (CNG). If an active speech frame is detected, the frame is subjected to a second classifier to discriminate unvoiced frames. If the classifier classifies the frame as unvoiced speech signal, the classification chain ends, and the frame is encoded using a coding method optimized for unvoiced signals. Otherwise, the frame is processed through a "stable voiced" classification module. If the frame is classified as stable voiced frame, then the frame is encoded using a coding method optimized for stable voiced signals. Otherwise, the frame is likely to contain a non-stationary signal segment such as a voiced onset or rapidly evolving voiced signal. These frames typically require a general purpose coder and high bit rate for sustaining good subjective quality. The disclosed gain quantization technique has been developed and optimized for stable voiced and general-purpose frames. However, it can be easily extended for any other signal class.

[0071] In the following, the classification of unvoiced and voiced signal frames will be described.

[0072] The unvoiced parts of the sound signal are characterized by missing periodic component and can be further divided into unstable frames, where energy and spectrum change rapidly, and stable frames where these characteristics remain relatively stable. The classification of unvoiced frames uses the following parameters:

- voicing measure \bar{r}_x , computed as an averaged normalized correlation;
- average spectral tilt measure (\bar{e}_t);
- maximum short-time energy increase at low level (\bar{e}_l) to efficiently detect explosive signal segments;
- maximum short-time energy variation (dE) used to assess frame stability;
- tonal stability to discriminate music from unvoiced signal as described in [Jelinek, M., Vaillancourt, T., Gibbs, J., "G.718: A new embedded speech and audio coding standard with high resilience to error-prone transmission channels", In IEEE Communications Magazine, vol. 47, pp. 117-123, October 2009]; and
- relative frame energy (E_{rel}) to detect very low-energy signals.

Voicing measure

[0073] The normalized correlation, used to determine the voicing measure, is computed as part of the open-loop pitch analysis. In the art of CELP coding, the open-loop search module usually outputs two estimates per frame. Here, it is also used to output the normalized correlation measures. These normalized correlations are computed on a weighted signal and a past weighted signal at the open-loop pitch delay. The weighted speech signal $s_w(n)$ is computed using a perceptual weighting filter. For example, a perceptual weighting filter with fixed denominator, suited for wideband signals, is used. An example of a transfer function of the perceptual weighting filter is given by the following relation:

$$W(z) = \frac{A(z/\gamma_1)}{1 - \gamma_2 z^{-1}},$$

where $0 < \gamma_2 < \gamma_1 \leq 1$

where $A(z)$ is a transfer function of linear prediction (LP) filter computed by means of the Levinson-Durbin algorithm and is given by the following relation

$$A(z) = 1 + \sum_{i=1}^p a_i z^{-i} .$$

5 [0074] LP analysis and open-loop pitch analysis are well known in the art of CELP coding and, accordingly, will not be further described in the present description.

[0075] The voicing measure \bar{r}_x is defined as an average normalized correlation given by the following relation:

$$10 \quad \bar{C}_{norm} = \frac{1}{3} (C_{norm}(d_0) + C_{norm}(d_1) + C_{norm}(d_2))$$

15 where $C_{norm}(d_0)$, $C_{norm}(d_1)$ and $C_{norm}(d_2)$ are, respectively, the normalized correlation of the first half of the current frame, the normalized correlation of the second half of the current frame, and the normalized correlation of the look-ahead (the beginning of the next frame). The arguments to the correlations are the open-loop pitch lags.

Spectral tilt

20 [0076] The spectral tilt contains information about a frequency distribution of energy. The spectral tilt can be estimated in the frequency domain as a ratio between the energy concentrated in low frequencies and the energy concentrated in high frequencies. However, it can be also estimated in different ways such as a ratio between the two first autocorrelation coefficients of the signal.

25 [0077] The energy in high frequencies and low frequencies is computed following the perceptual critical bands as described in [J. D. Johnston, "Transform Coding of Audio Signals Using Perceptual Noise Criteria," IEEE Journal on Selected Areas in Communications, vol. 6, no. 2, pp. 314-323, February 1988]. The energy in high frequencies is calculated as the average energy of the last two critical bands using the following relation:

$$30 \quad \bar{E}_h = 0.5 [E_{CB}(b_{max} - 1) + E_{CB}(b_{max})]$$

where $E_{CB}(i)$ is the critical band energy of i th band and b_{max} is the last critical band. The energy in low frequencies is computed as average energy of the first 10 critical bands using the following relation:

$$35 \quad \bar{E}_l = \frac{1}{10 - b_{min}} \sum_{i=b_{min}}^9 E_{CB}(i)$$

where b_{min} is the first critical band.

40 [0078] The middle critical bands are excluded from the calculation as they do not tend to improve the discrimination between frames with high energy concentration in low frequencies (generally voiced) and with high energy concentration in high frequencies (generally unvoiced). In between, the energy content is not characteristic for any of the classes discussed further and increases the decision confusion.

45 [0079] The spectral tilt is given by

$$e_i = \frac{\bar{E}_l - \bar{N}_l}{\bar{E}_h - \bar{N}_h}$$

50 where \bar{N}_h and \bar{N}_l are, respectively, the average noise energies in the last two critical bands and first 10 critical bands, computed in the same way as \bar{E}_h and \bar{E}_l . The estimated noise energies have been added to the tilt computation to account for the presence of background noise. The spectral tilt computation is performed twice per frame and average spectral tilt is calculated which is then used in unvoiced frame classification. That is

55

$$\bar{e}_t = \frac{1}{3} (e_{old} + e_t(0) + e_t(1)),$$

5 where e_{old} is the spectral tilt in the second half of the previous frame.

Maximum short-time energy increase at low level

10 [0080] The maximum short-time energy increase at low level $dE0$ is evaluated on the input sound signal $s(n)$, where $n=0$ corresponds to the first sample of the current frame. Signal energy is evaluated twice per sub-frame. Assuming for example the scenario of four sub-frames per frame, the energy is calculated 8 times per frame. If the total frame length is, for example, 256 samples, each of these short segments may have 32 samples. In the calculation, short-term energies of the last 32 samples from the previous frame and the first 32 samples from the next frame are also taken into consideration. The short-time energies are calculated using the following relations:

15

$$E_{st}^{(1)}(j) = \max_{i=0}^{31} (s^2(i + 32j)), \quad j=-1, \dots, 8,$$

20 where $j=-1$ and $j=8$ correspond to the end of the previous frame and the beginning of the next frame, respectively. Another set of nine short-term energies is calculated by shifting the signal indices in the previous equation by 16 samples using the following relation:

25

$$E_{st}^{(2)}(j) = \max_{i=0}^{31} (s^2(i + 32j - 16)), \quad j=0, \dots, 8.$$

30 [0081] For energies that are sufficiently low, i.e. which fulfill the condition $10 \log(E_{st}^{(j)}(j)) < 37$, the following ratio is calculated

35

$$rat^{(1)}(j) = \frac{E_{st}^{(1)}(j+1)}{E_{st}^{(1)}(j)}, \quad \text{for } j=-1, \dots, 6,$$

40 for the first set of energies and the same calculation is repeated for $E_{st}^{(2)}(j)$ with $j=0, \dots, 7$ to obtain two sets of ratios $rat^{(1)}$ and $rat^{(2)}$. The only maximum in these two sets is searched by

40

$$dE0 = \max(rat^{(1)}, rat^{(2)})$$

45 which is the maximum short-time energy increase at low level.

Maximum short-time energy variation

50 [0082] This parameter dE is similar to the maximum short-time energy increase at low level with the difference that the low-level condition is not applied. Thus, the parameter is computed as the maximum of the following four values:

50

$$E_{st}^{(1)}(0) / E_{st}^{(1)}(-1)$$

55

$$E_{st}^{(1)}(7) / E_{st}^{(1)}(8)$$

$$\frac{\max(E_{st}^{(1)}(j), E_{st}^{(1)}(j-1))}{\min(E_{st}^{(1)}(j), E_{st}^{(1)}(j-1))} \quad \text{for } j=1, \dots, 7$$

$$\frac{\max(E_{st}^{(2)}(j), E_{st}^{(2)}(j-1))}{\min(E_{st}^{(2)}(j), E_{st}^{(2)}(j-1))} \quad \text{for } j=1, \dots, 8.$$

Unvoiced signal classification

[0083] The classification of unvoiced signal frames is based on the parameters described above, namely: the voicing measure \bar{r}_x , the average spectral tilt \bar{e}_t , the maximum short-time energy increase at low level $dE0$ and the maximum short-time energy variation dE . The algorithm is further supported by the tonal stability parameter, the SAD flag and the relative frame energy calculated during the noise energy update phase. For more detailed information about these parameters, see for example [Jelinek, M., et al., "Advances in source-controlled variable bitrate wideband speech coding", Special Workshop in MAUI (SWIM): Lectures by masters in speech processing, Maui, Hawaii, January 12-14, 2004].

[0084] The relative frame energy is given by

$$E_{rel} = E_t - \bar{E}_f$$

where E_t is the total frame energy (in dB) and \bar{E}_f is the long-term average frame energy, updated during each active frame by $\bar{E}_f = 0.99\bar{E}_f + 0.01E_t$.

[0085] The rules for unvoiced classification of wideband signals are summarized below

[[$(\bar{r}_x < 0.695)$ AND $(\bar{e}_t < 4.0)$] OR $(E_{rel} < -14)$] AND

[last frame INACTIVE OR UNVOICED OR $(e_{old} < 2.4)$ AND $(r_x(0) < 0.66)$]

[$dE0 < 250$] AND

[$e_t(1) < 2.7$] AND

NOT [(*tonal_stability* AND $(\bar{r}_x > 0.52)$ AND $(\bar{e}_t > 0.5)$) OR $(\bar{e}_t > 0.85)$] AND $(E_{rel} > -14)$ AND SAD flag set to 1]

[0086] The first line of this condition is related to low-energy signals and signals with low correlation concentrating their energy in high frequencies. The second line covers voiced offsets, the third line covers explosive signal segments and the fourth line is related to voiced onsets. The last line discriminates music signals that would be otherwise declared as unvoiced.

[0087] If the combined conditions are fulfilled the classification ends by declaring the current frame as unvoiced.

Voiced signal classification

[0088] If a frame is not classified as inactive frame or as unvoiced frame then it is tested if it is a stable voiced frame. The decision rule is based on the normalized correlation \bar{r}_x in each sub-frame (with 1/4 subsample resolution), the average spectral tilt \bar{e}_t and open-loop pitch estimates in all sub-frames (with 1/4 subsample resolution).

[0089] The open-loop pitch estimation procedure calculates three open-loop pitch lags: d_0 , d_1 and d_2 , corresponding to the first half-frame, the second half-frame and the look-ahead (first half-frame of the following frame). In order to obtain a precise pitch information in all four sub-frames, 1/4 sample resolution fractional pitch refinement is calculated. This refinement is calculated on a perceptually weighted input signal $s_{wd}(n)$ (for example the input sound signal $s(n)$ filtered through the above described perceptual weighting filter). At the beginning of each sub-frame a short correlation analysis (40 samples) with resolution of 1 sample is performed in the interval $(-7, +7)$ using the following delays: d_0 for the first and second sub-frames and d_1 for the third and fourth sub-frames. The correlations are then interpolated around their maxima at the fractional positions $d_{max} - 3/4$, $d_{max} - 1/2$, $d_{max} - 1/4$, d_{max} , $d_{max} + 1/4$, $d_{max} + 1/2$, $d_{max} + 3/4$. The value yielding the maximum correlation is chosen as the refined pitch lag.

[0090] Let the refined open-loop pitch lags in all four sub-frames be denoted as $T(0)$, $T(1)$, $T(2)$ and $T(3)$ and their corresponding normalized correlations as $C(0)$, $C(1)$, $C(2)$ and $C(3)$. Then, the voiced signal classification condition is given by

[$C(0) > 0.605$] AND

[$C(1) > 0.605$] AND

[C(2) > 0.605] AND
 [C(3) > 0.605] AND
 $[\bar{e}_r > 4]$ AND

5 [|T(1) - T(0)|] < 3 AND
 [|T(2) - T(1)|] < 3 AND
 [|T(3) - T(2)|] < 3

10 **[0091]** The above voiced signal classification condition indicates that the normalized correlation must be sufficiently high in all sub-frames, the pitch estimates must not diverge throughout the frame and the energy must be concentrated in low frequencies. If this condition is fulfilled the classification ends by declaring the current frame as voiced. Otherwise the current frame is declared as generic.

[0092] Although the present invention has been described in the foregoing description with reference to non-restrictive illustrative embodiments thereof, these embodiments can be modified at will within the scope of the appended claims.

15 Claims

1. A device for quantizing a gain of a fixed contribution of an excitation in a frame, including sub-frames, of a coded sound signal, comprising:

20 an input for a parameter representative of a classification of the frame;
 an estimator of the gain of the fixed contribution of the excitation in a sub-frame of said frame, using the parameter representative of the classification of the frame; and
 a predictive quantizer of the gain of the fixed contribution of the excitation, in the sub-frame, using the estimated gain;
 25 wherein the predictive quantizer determines a correction factor for the estimated gain as a quantization of the gain of the fixed contribution of the excitation;
 wherein the estimated gain multiplied by the correction factor gives the quantized gain of the fixed contribution of the excitation; and
 wherein the estimator comprises, for a first sub-frame of the frame:

30 (a) a first calculator of a linear estimation of the gain of the fixed contribution of the excitation in logarithmic domain in response to the parameter representative of the classification of the frame;
 (b) a subtractor of an energy of a filtered innovation codevector from a fixed codebook in logarithmic domain from the linear gain estimation from the first calculator, the subtractor producing a gain in logarithmic domain;
 35 (c) a converter of the gain in logarithmic domain from the subtractor to linear domain to produce the estimated gain; and
 (d) a multiplier of the estimated gain by the correction factor to produce the quantized gain of the fixed contribution of the excitation; and

40 wherein the estimator, for each sub-frame of said frame following the first sub-frame, is responsive to the parameter representative of the classification of the frame and gains of adaptive and fixed contributions of the excitation of at least one previous sub-frame of the frame to estimate the gain of the fixed contribution of the excitation.

45 2. The quantizing device according to claim 1, wherein:

50 the estimator comprises, for each sub-frame following the first sub-frame, a second calculator of a linear estimation of the gain of the fixed contribution of the excitation in logarithmic domain and a converter of the linear estimation in logarithmic domain in linear domain to produce the estimated gain;
 and wherein the gains of the adaptive and fixed contributions of the excitation of at least one previous sub-frame of the frame are quantized gains; and
 the quantized gains of the adaptive contributions of the excitation are supplied to the second calculator directly while the quantized gains of the fixed contributions of the excitation are supplied to the second calculator in logarithmic domain through a logarithm calculator.

55 3. The quantizing device according to claim 1 or 2, wherein the estimator uses, for estimating the gain of the fixed contribution of the excitation, estimation coefficients different for each sub-frame of the frame.

4. A device for jointly quantizing gains of adaptive and fixed contributions of an excitation in a frame of a coded sound signal, comprising:

a quantizer of the gain of the adaptive contribution of the excitation; and
the device for quantizing the gain of the fixed contribution of the excitation as defined in any one of claims 1 to 3.

5. The device for jointly quantizing the gains of the adaptive and fixed contributions of the excitation according to claim 4, comprising a gain codebook having entries each comprising the quantized gain of the adaptive contribution of the excitation and a correction factor for the estimated gain.

6. The device for jointly quantizing the gains of the adaptive and fixed contributions of the excitation according to claim 5, wherein the quantizer of the gain of the adaptive contribution of the excitation and the predictive quantizer of the gain of the fixed contribution of the excitation search the gain codebook and select the gain of the adaptive contribution of the excitation from one entry of the gain codebook and the correction factor of the same entry of the gain codebook as a quantization of the gain of the fixed contribution of the excitation.

7. The device for jointly quantizing the gains of the adaptive and fixed contributions of the excitation according to claim 5, comprising a designer of the gain codebook for each sub-frame of the frame.

8. The device for jointly quantizing the gains of the adaptive and fixed contributions of the excitation according to claim 7, wherein the gain codebook has different sizes in different sub-frames of the frame.

9. A device for retrieving a quantized gain of a fixed contribution of an excitation in a sub-frame of a frame, comprising:

a receiver of a gain codebook index;
an estimator of the gain of the fixed contribution of the excitation in the sub-frame, using a parameter representative of a classification of the frame;
a gain codebook for supplying a correction factor in response to the gain codebook index; and
a multiplier of the estimated gain by the correction factor to provide a quantized gain of the fixed contribution of the excitation in said sub-frame;
wherein the estimator comprises, for a first sub-frame of the frame:

- (a) a calculator of a linear estimation of the gain of the fixed contribution of the excitation in logarithmic domain in response to the parameter representative of the classification of the frame;
- (b) a subtractor of an energy of a filtered innovation codevector from a fixed codebook in logarithmic domain from the linear gain estimation from the calculator, the subtractor producing a gain in logarithmic domain; and
- (c) a converter of the gain in logarithmic domain from the subtractor to linear domain to produce the estimated gain; and

wherein the estimator, for each sub-frame of said frame following the first sub-frame, is responsive to the parameter representative of the classification of the frame and gains of adaptive and fixed contributions of the excitation of at least one previous sub-frame of the frame to estimate the gain of the fixed contribution of the excitation.

10. A device for retrieving quantized gains of adaptive and fixed contributions of an excitation in a sub-frame of a frame, comprising:

a receiver of a gain codebook index;
an estimator of the gain of the fixed contribution of the excitation in the sub-frame, using a parameter representative of a classification of the frame;
a gain codebook for supplying the quantized gain of the adaptive contribution of the excitation and a correction factor for the sub-frame in response to the gain codebook index; and
a multiplier of the estimated gain by the correction factor to provide a quantized gain of the fixed contribution of the excitation in the sub-frame;
wherein the estimator comprises, for a first sub-frame of the frame:

- (a) a calculator of a linear estimation of the gain of the fixed contribution of the excitation in logarithmic domain in response to the parameter representative of the classification of the frame;

(b) a subtractor of an energy of a filtered innovation codevector from a fixed codebook in logarithmic domain from the linear gain estimation from the calculator, the subtractor producing a gain in logarithmic domain; and
 (c) a converter of the gain in logarithmic domain from the subtractor to linear domain to produce the estimated gain; and

5

wherein the estimator, for each sub-frame of said frame following the first sub-frame, is responsive to the parameter representative of the classification of the frame and gains of adaptive and fixed contributions of the excitation of at least one previous sub-frame of the frame to estimate the gain of the fixed contribution of the excitation.

10

11. The device for retrieving the quantized gains of the adaptive and fixed contributions of the excitation according to claim 10, wherein the gain codebook comprises entries each comprising the quantized gain of the adaptive contribution of the excitation and the correction factor for the estimated gain.

15

12. A method for quantizing a gain of a fixed contribution of an excitation in a frame, including sub-frames, of a coded sound signal, comprising:

receiving a parameter representative of a classification of the frame;
 estimating the gain of the fixed contribution of the excitation in a sub-frame of said frame, using the parameter representative of the classification of the frame; and
 predictive quantizing the gain of the fixed contribution of the excitation, in the sub-frame, using the estimated gain; wherein predictive quantizing the gain of the fixed contribution of the excitation comprises determining a correction factor for the estimated gain as a quantization of the gain of the fixed contribution of the excitation; wherein the estimated gain multiplied by the correction factor gives the quantized gain of the fixed contribution of the excitation; and
 wherein estimating the gain of the fixed contribution of the excitation comprises, for a first sub-frame of the frame:

20

25

(a) calculating a linear estimation of the gain of the fixed contribution of the excitation in logarithmic domain in response to the parameter representative of the classification of the frame;
 (b) subtracting an energy of a filtered innovation codevector from a fixed codebook in logarithmic domain from the linear gain estimation to produce a gain in logarithmic domain;
 (c) converting the gain in logarithmic domain from the subtraction to linear domain to produce the estimated gain; and
 (d) multiplying the estimated gain by the correction factor to produce the quantized gain of the fixed contribution of the excitation; and

30

35

wherein estimating the gain of the fixed contribution of the excitation, for each sub-frame of said frame following the first sub-frame, is responsive to the parameter representative of the classification of the frame and gains of adaptive and fixed contributions of the excitation of at least one previous sub-frame of the frame to estimate the gain of the fixed contribution of the excitation.

40

13. The quantizing method according to claim 12, wherein estimating the gain of the fixed contribution of the excitation comprises, for each sub-frame following the first sub-frame, calculating a linear estimation of the gain of the fixed contribution of the excitation in logarithmic domain and converting the linear estimation in logarithmic domain in linear domain to produce the estimated gain, and wherein the gains of the adaptive contributions of the excitation of at least one previous sub-frame of the frame are quantized gains and the gains of the fixed contributions of the excitation of at least one previous sub-frame of the frame are quantized gains in logarithmic domain.

45

14. The quantizing method according to claim 12 or 13, wherein estimating the gain of the fixed contribution of the excitation comprises using, for estimating the gain of the fixed contribution of the excitation, estimation coefficients different for each sub-frame of the frame.

50

15. A method for jointly quantizing gains of adaptive and fixed contributions of an excitation in a frame of a coded sound signal, comprising:

55

quantizing the gain of the adaptive contribution of the excitation; and
 quantizing the gain of the fixed contribution of the excitation using the method as defined in any one of claims 12 to 14.

16. The method for jointly quantizing the gains of the adaptive and fixed contributions of the excitation according to claim 15, using a gain codebook having entries each comprising the quantized gain of the adaptive contribution of the excitation and a correction factor for the estimated gain.

5 17. The method for jointly quantizing the gains of the adaptive and fixed contributions of the excitation according to claim 16, wherein quantizing the gain of the adaptive contribution of the excitation and quantizing the gain of the fixed contribution of the excitation comprises searching the gain codebook and selecting the gain of the adaptive contribution of the excitation from one entry of the gain codebook and the correction factor of the same entry of the gain codebook as a quantization of the gain of the fixed contribution of the excitation.

10 18. A method for retrieving a quantized gain of a fixed contribution of an excitation in a sub-frame of a frame, comprising:

receiving a gain codebook index;
 15 estimating the gain of the fixed contribution of the excitation in the sub-frame, using a parameter representative of a classification of the frame;
 supplying, from a gain codebook and for the sub-frame, a correction factor in response to the gain codebook index; and
 multiplying the estimated gain by the correction factor to provide a quantized gain of the fixed contribution of the excitation in said sub-frame; and
 20 wherein estimating the gain of the fixed contribution of the excitation comprises, for a first sub-frame of the frame:

- (a) calculating a linear estimation of the gain of the fixed contribution of the excitation in logarithmic domain in response to the parameter representative of the classification of the frame;
- 25 (b) subtracting an energy of a filtered innovation codevector from a fixed codebook in logarithmic domain from the linear gain estimation to produce a gain in logarithmic domain; and
- (c) converting the gain in logarithmic domain from the subtraction to linear domain to produce the estimated gain; and

30 wherein estimating the gain of the fixed contribution of the excitation comprises using, in each sub-frame of said frame following the first sub-frame, the parameter representative of the classification of the frame and gains of adaptive and fixed contributions of the excitation of at least one previous sub-frame of the frame to estimate the gain of the fixed contribution of the excitation.

35 19. The method for retrieving the quantized gain of the fixed contribution of the claim excitation according to 18, wherein estimating the gain of the fixed contribution of the excitation comprises using estimation coefficients different for each sub-frame of the frame.

40 20. A method for retrieving quantized gains of adaptive and fixed contributions of an excitation in a sub-frame of a frame, comprising:

receiving a gain codebook index;
 estimating the gain of the fixed contribution of the excitation in the sub-frame, using a parameter representative of a classification of the frame;
 45 supplying, from a gain codebook and for the sub-frame, the quantized gain of the adaptive contribution of the excitation and a correction factor in response to the gain codebook index; and
 multiplying the estimated gain by the correction factor to provide a quantized gain of the fixed contribution of the excitation in said sub-frame; and
 wherein estimating the gain of the fixed contribution of the excitation comprises, for a first sub-frame of the frame:

- 50 (a) calculating a linear estimation of the gain of the fixed contribution of the excitation in logarithmic domain in response to the parameter representative of the classification of the frame;
- (b) subtracting an energy of a filtered innovation codevector from a fixed codebook in logarithmic domain from the linear gain estimation to produce a gain in logarithmic domain; and
- 55 (c) converting the gain in logarithmic domain from the subtraction to linear domain to produce the estimated gain; and

wherein estimating the gain of the fixed contribution of the excitation comprises using, in each sub-frame of said frame following the first sub-frame, the parameter representative of the classification of the frame and gains

of adaptive and fixed contributions of the excitation of at least one previous sub-frame of the frame to estimate the gain of the fixed contribution of the excitation .

- 5 **21.** The method for retrieving the quantized gains of the adaptive and fixed contributions of the excitation according to claim 20, wherein the gain codebook comprises entries each comprising the quantized gain of the adaptive contribution of the excitation and the correction factor for the estimated gain.

10 **Patentansprüche**

1. Vorrichtung zum Quantisieren einer Verstärkung eines festen Beitrags einer Anregung in einem Unterrahmen einschließenden Rahmen eines codierten Tonsignals, umfassend:

15 einen Eingang für einen Parameter, der für eine Klassifizierung des Rahmens repräsentativ ist;
 einen Schätzer der Verstärkung des festen Beitrags der Anregung in einem Unterrahmen des Rahmens unter Verwendung des Parameters, der für die Klassifizierung des Rahmens repräsentativ ist; und
 einen prädiktiven Quantisierer der Verstärkung des festen Beitrags der Anregung im Unterrahmen unter Verwendung der geschätzten Verstärkung;
 wobei der prädiktive Quantisierer einen Korrekturfaktor für die geschätzte Verstärkung als eine Quantisierung
 20 der Verstärkung des festen Beitrags der Anregung bestimmt;
 wobei die geschätzte Verstärkung mit dem Korrekturfaktor multipliziert die quantisierte Verstärkung des festen Beitrags der Anregung ergibt; und
 wobei der Schätzer für einen ersten Unterrahmen des Rahmens umfasst:

- 25 (a) einen ersten Berechner einer linearen Schätzung der Verstärkung des festen Beitrags der Anregung im logarithmischen Bereich in Reaktion auf den Parameter, der für die Klassifizierung des Rahmens repräsentativ ist;
 (b) einen Subtrahierer einer Energie eines gefilterten Innovations-Codevektors aus einem festen Codebuch im logarithmischen Bereich von der linearen Verstärkungsschätzung aus dem ersten Berechner, wobei der
 30 Subtrahierer eine Verstärkung im logarithmischen Bereich erzeugt;
 (c) einen Wandler der Verstärkung im logarithmischen Bereich aus dem Subtrahierer in den linearen Bereich, um die geschätzte Verstärkung zu erzeugen; und
 (d) einen Multiplizierer der geschätzten Verstärkung mit dem Korrekturfaktor, um die quantisierte Verstärkung des festen Beitrags der Anregung zu erzeugen; und

35 wobei der Schätzer für jeden Unterrahmen des Rahmens, der dem ersten Unterrahmen folgt, auf den Parameter, der für die Klassifizierung des Rahmens repräsentativ ist, und Verstärkungen von adaptiven und festen Beiträgen der Anregung mindestens eines vorhergehenden Unterrahmens des Rahmens reagiert, um die Verstärkung des festen Beitrags der Anregung zu schätzen.

- 40 **2.** Quantisierungsvorrichtung nach Anspruch 1, wobei:

45 der Schätzer für jeden Unterrahmen, der dem ersten Unterrahmen folgt, einen zweiten Berechner einer linearen Schätzung der Verstärkung des festen Beitrags der Anregung im logarithmischen Bereich und einen Wandler der linearen Schätzung im logarithmischen Bereich in den linearen Bereich umfasst, um die geschätzte Verstärkung zu erzeugen;
 und wobei die Verstärkungen der adaptiven und festen Beiträge der Anregung mindestens eines vorhergehenden Unterrahmens des Rahmens quantisierte Verstärkungen sind; und
 die quantisierten Verstärkungen der adaptiven Beiträge der Anregung dem zweiten Berechner direkt geliefert werden, während die quantisierten Verstärkungen der festen Beiträge der Anregung dem zweiten Berechner
 50 im logarithmischen Bereich über einen Logarithmusrechner geliefert werden.

- 55 **3.** Quantisierungsvorrichtung nach Anspruch 1 oder 2, wobei der Schätzer zum Schätzen der Verstärkung des festen Beitrags der Anregung Schätzkoeffizienten verwendet, die für jeden Unterrahmen des Rahmens unterschiedlich sind.

- 4.** Vorrichtung zum gemeinsamen Quantisieren von Verstärkungen von adaptiven und festen Beiträgen einer Anregung in einem Rahmen eines codierten Tonsignals, umfassend:

einen Quantisierer der Verstärkung des adaptiven Beitrags der Anregung; und die Vorrichtung zum Quantisieren der Verstärkung des festen Beitrags der Anregung, wie in einem der Ansprüche 1 bis 3 definiert.

5 5. Vorrichtung zum gemeinsamen Quantisieren der Verstärkungen der adaptiven und festen Beiträge der Anregung nach Anspruch 4, die ein Verstärkungs-Codebuch umfasst, das Einträge aufweist, die jeder die quantisierte Verstärkung des adaptiven Beitrags der Anregung und einen Korrekturfaktor für die geschätzte Verstärkung umfassen.

10 6. Vorrichtung zum gemeinsamen Quantisieren der Verstärkungen der adaptiven und festen Beiträge der Anregung nach Anspruch 5, wobei der Quantisierer der Verstärkung des adaptiven Beitrags der Anregung und der prädiktive Quantisierer der Verstärkung des festen Beitrags der Anregung das Verstärkungs-Codebuch durchsuchen und die Verstärkung des adaptiven Beitrags der Anregung aus einem Eintrag des Verstärkungs-Codebuchs, und den Korrekturfaktor des gleichen Eintrags des Verstärkungs-Codebuchs als eine Quantisierung der Verstärkung des festen Beitrags der Anregung auswählen.

15 7. Vorrichtung zum gemeinsamen Quantisieren der Verstärkungen der adaptiven und festen Beiträge der Anregung nach Anspruch 5, die für jeden Unterrahmen des Rahmens einen Designer des Verstärkungs-Codebuchs umfasst.

20 8. Vorrichtung zum gemeinsamen Quantisieren der Verstärkungen der adaptiven und festen Beiträge der Anregung nach Anspruch 7, wobei das Verstärkungs-Codebuch in unterschiedlichen Unterrahmen des Rahmens unterschiedliche Größen aufweist.

25 9. Vorrichtung zum Abrufen einer quantisierten Verstärkung eines festen Beitrags einer Anregung in einem Unterrahmen eines Rahmens, umfassend:

einen Empfänger eines Verstärkungs-Codebuchindex;
einen Schätzer der Verstärkung des festen Beitrags der Anregung im Unterrahmen unter Verwendung eines Parameters, der für eine Klassifizierung des Rahmens repräsentativ ist;
ein Verstärkungs-Codebuch zum Liefern eines Korrekturfaktors in Reaktion auf den Verstärkungs-Codebuchindex; und
30 einen Multiplizierer der geschätzten Verstärkung mit dem Korrekturfaktor, um eine quantisierte Verstärkung des festen Beitrags der Anregung im Unterrahmen bereitzustellen;
wobei der Schätzer für einen ersten Unterrahmen des Rahmens umfasst:

- 35 (a) einen Berechner einer linearen Schätzung der Verstärkung des festen Beitrags der Anregung im logarithmischen Bereich in Reaktion auf den Parameter, der für die Klassifizierung des Rahmens repräsentativ ist;
(b) einen Subtrahierer einer Energie eines gefilterten Innovations-Codevektors aus einem festen Codebuch im logarithmischen Bereich von der linearen Verstärkungsschätzung aus dem Berechner, wobei der Subtrahierer eine Verstärkung im logarithmischen Bereich erzeugt; und
40 (c) einen Wandler der Verstärkung im logarithmischen Bereich aus dem Subtrahierer in den linearen Bereich, um die geschätzte Verstärkung zu erzeugen; und

wobei der Schätzer für jeden Unterrahmen des Rahmens, der dem ersten Unterrahmen folgt, auf den Parameter, der für die Klassifizierung des Rahmens repräsentativ ist, und Verstärkungen von adaptiven und festen Beiträgen der Anregung mindestens eines vorhergehenden Unterrahmens des Rahmens reagiert, um die Verstärkung des festen Beitrags der Anregung zu schätzen.

50 10. Vorrichtung zum Abrufen von quantisierten Verstärkungen von adaptiven und festen Beiträgen einer Anregung in einem Unterrahmen eines Rahmens, umfassend:

einen Empfänger eines Verstärkungs-Codebuchindex;
einen Schätzer der Verstärkung des festen Beitrags der Anregung im Unterrahmen unter Verwendung eines Parameters, der für eine Klassifizierung des Rahmens repräsentativ ist;
55 ein Verstärkungs-Codebuch zum Liefern der quantisierten Verstärkung des adaptiven Beitrags der Anregung und eines Korrekturfaktors für den Unterrahmen in Reaktion auf den Verstärkungs-Codebuchindex; und
einen Multiplizierer der geschätzten Verstärkung mit dem Korrekturfaktor, um eine quantisierte Verstärkung des festen Beitrags der Anregung im Unterrahmen bereitzustellen;

wobei der Schätzer für einen ersten Unterrahmen des Rahmens umfasst:

- (a) einen Berechner einer linearen Schätzung der Verstärkung des festen Beitrags der Anregung im logarithmischen Bereich in Reaktion auf den Parameter, der für die Klassifizierung des Rahmens repräsentativ ist;
- (b) einen Subtrahierer einer Energie eines gefilterten Innovations-Codevektors aus einem festen Codebuch im logarithmischen Bereich von der linearen Verstärkungsschätzung aus dem Berechner, wobei der Subtrahierer eine Verstärkung im logarithmischen Bereich erzeugt; und
- (c) einen Wandler der Verstärkung im logarithmischen Bereich aus dem Subtrahierer in den linearen Bereich, um die geschätzte Verstärkung zu erzeugen; und

wobei der Schätzer für jeden Unterrahmen des Rahmens, der dem ersten Unterrahmen folgt, auf den Parameter, der für die Klassifizierung des Rahmens repräsentativ ist, und Verstärkungen von adaptiven und festen Beiträgen der Anregung mindestens eines vorhergehenden Unterrahmens des Rahmens reagiert, um die Verstärkung des festen Beitrags der Anregung zu schätzen.

11. Vorrichtung zum Abrufen der quantisierten Verstärkungen der adaptiven und festen Beiträge der Anregung nach Anspruch 10, wobei das Verstärkungs-Codebuch Einträge umfasst, die jeder die quantisierte Verstärkung des adaptiven Beitrags der Anregung und den Korrekturfaktor für die geschätzte Verstärkung umfassen.

12. Verfahren zum Quantisieren einer Verstärkung eines festen Beitrags einer Anregung in einem Unterrahmen einschließenden Rahmen eines codierten Tonsignals, umfassend:

Empfangen eines Parameters, der für eine Klassifizierung des Rahmens repräsentativ ist;
 Schätzen der Verstärkung des festen Beitrags der Anregung in einem Unterrahmen des Rahmens unter Verwendung des Parameters, der für die Klassifizierung des Rahmens repräsentativ ist; und
 prädiktives Quantisieren der Verstärkung des festen Beitrags der Anregung im Unterrahmen unter Verwendung der geschätzten Verstärkung;
 wobei das prädiktive Quantisieren der Verstärkung des festen Beitrags der Anregung das Bestimmen eines Korrekturfaktors für die geschätzte Verstärkung als eine Quantisierung der Verstärkung des festen Beitrags der Anregung umfasst;
 wobei die geschätzte Verstärkung mit dem Korrekturfaktor multipliziert die quantisierte Verstärkung des festen Beitrags der Anregung ergibt; und
 wobei das Schätzen der Verstärkung des festen Beitrags der Anregung für einen ersten Unterrahmen des Rahmens umfasst:

- (a) Berechnen einer linearen Schätzung der Verstärkung des festen Beitrags der Anregung im logarithmischen Bereich in Reaktion auf den Parameter, der für die Klassifizierung des Rahmens repräsentativ ist;
- (b) Subtrahieren einer Energie eines gefilterten Innovations-Codevektors aus einem festen Codebuch im logarithmischen Bereich von der linearen Verstärkungsschätzung, um eine Verstärkung im logarithmischen Bereich zu erzeugen;
- (c) Umwandeln der Verstärkung im logarithmischen Bereich aus dem Subtrahierer in den linearen Bereich, um die geschätzte Verstärkung zu erzeugen; und
- (d) Multiplizieren der geschätzten Verstärkung mit dem Korrekturfaktor, um die quantisierte Verstärkung des festen Beitrags der Anregung zu erzeugen; und

wobei das Schätzen der Verstärkung des festen Beitrags der Anregung für jeden Unterrahmen des Rahmens, der dem ersten Unterrahmen folgt, auf den Parameter, der für die Klassifizierung des Rahmens repräsentativ ist, und Verstärkungen von adaptiven und festen Beiträgen der Anregung mindestens eines vorhergehenden Unterrahmens des Rahmens reagiert, um die Verstärkung des festen Beitrags der Anregung zu schätzen.

13. Quantisierungsverfahren nach Anspruch 12, wobei das Schätzen der Verstärkung des festen Beitrags der Anregung für jeden Unterrahmen, der dem ersten Unterrahmen folgt, das Berechnen einer linearen Schätzung der Verstärkung des festen Beitrags der Anregung im logarithmischen Bereich, und Umwandeln der linearen Schätzung im logarithmischen Bereich in den linearen Bereich umfasst, um die geschätzte Verstärkung zu erzeugen, und wobei die Verstärkungen der adaptiven Beiträge der Anregung mindestens eines vorhergehenden Unterrahmens des Rahmens quantisierte Verstärkungen sind, und die Verstärkungen der festen Beiträge der Anregung mindestens eines vorhergehenden Unterrahmens des Rahmens quantisierte Verstärkungen im logarithmischen Bereich sind.

14. Quantisierungsverfahren nach Anspruch 12 oder 13, wobei das Schätzen der Verstärkung des festen Beitrags der Anregung das Verwenden von Schätzkoeffizienten zum Schätzen der Verstärkung des festen Beitrags der Anregung umfasst, die für jeden Unterrahmen des Rahmens unterschiedlich sind.
- 5 15. Verfahren zum gemeinsamen Quantisieren von Verstärkungen von adaptiven und festen Beiträgen einer Anregung in einem Rahmen eines codierten Tonsignals, umfassend:
- Quantisieren der Verstärkung des adaptiven Beitrags der Anregung; und
Quantisieren der Verstärkung des festen Beitrags der Anregung unter Verwendung des Verfahrens, wie in
10 in einem der Ansprüche 12 bis 14 definiert.
16. Verfahren zum gemeinsamen Quantisieren der Verstärkungen der adaptiven und festen Beiträge der Anregung nach Anspruch 15 unter Verwendung eines Verstärkungs-Codebuchs, das Einträge aufweist, die jeder die quantisierte Verstärkung des adaptiven Beitrags der Anregung und einen Korrekturfaktor für die geschätzte Verstärkung
15 umfassen.
17. Verfahren zum gemeinsamen Quantisieren der Verstärkungen der adaptiven und festen Beiträge der Anregung nach Anspruch 16, wobei das Quantisieren der Verstärkung des adaptiven Beitrags der Anregung und das Quantisieren der Verstärkung des festen Beitrags der Anregung das Durchsuchen des Verstärkungs-Codebuchs und
20 das Auswählen der Verstärkung des adaptiven Beitrags der Anregung aus einem Eintrag des Verstärkungs-Codebuchs, und des Korrekturfaktors des gleichen Eintrags des Verstärkungs-Codebuchs als eine Quantisierung der Verstärkung des festen Beitrags der Anregung umfasst.
18. Verfahren zum Abrufen einer quantisierten Verstärkung eines festen Beitrags einer Anregung in einem Unterrahmen
25 eines Rahmens, umfassend:
- Empfangen eines Verstärkungs-Codebuchindex;
Schätzen der Verstärkung des festen Beitrags der Anregung im Unterrahmen unter Verwendung eines Parameters, der für eine Klassifizierung des Rahmens repräsentativ ist;
30 Liefern eines Korrekturfaktors aus einem Verstärkungs-Codebuch und für den Unterrahmen in Reaktion auf den Verstärkungs-Codebuchindex; und
Multiplizieren der geschätzten Verstärkung mit dem Korrekturfaktor, um eine quantisierte Verstärkung des festen Beitrags der Anregung im Unterrahmen bereitzustellen; und
wobei das Schätzen der Verstärkung des festen Beitrags der Anregung für einen ersten Unterrahmen des
35 Rahmens umfasst:
- (a) Berechnen einer linearen Schätzung der Verstärkung des festen Beitrags der Anregung im logarithmischen Bereich in Reaktion auf den Parameter, der für die Klassifizierung des Rahmens repräsentativ ist;
40 (b) Subtrahieren einer Energie eines gefilterten Innovations-Codevektors aus einem festen Codebuch im logarithmischen Bereich von der linearen Verstärkungsschätzung, um eine Verstärkung im logarithmischen Bereich zu erzeugen; und
(c) Umwandeln der Verstärkung im logarithmischen Bereich aus dem Subtrahierer in den linearen Bereich, um die geschätzte Verstärkung zu erzeugen; und
- 45 wobei das Schätzen der Verstärkung des festen Beitrags der Anregung das Verwenden des Parameters, der für die Klassifizierung des Rahmens repräsentativ ist, und von Verstärkungen von adaptiven und festen Beiträgen der Anregung mindestens eines vorhergehenden Unterrahmens des Rahmens in jedem Unterrahmen des Rahmens, der dem ersten Unterrahmen folgt, umfasst, um die Verstärkung des festen Beitrags der Anregung
50 zu schätzen.
19. Verfahren zum Abrufen der quantisierten Verstärkung des festen Beitrags der Anregung nach Anspruch 18, wobei das Schätzen der Verstärkung des festen Beitrags der Anregung das Verwenden von Schätzkoeffizienten umfasst, die für jeden Unterrahmen des Rahmens unterschiedlich sind.
- 55 20. Verfahren zum Abrufen von quantisierten Verstärkungen von adaptiven und festen Beiträgen einer Anregung in einem Unterrahmen eines Rahmens, umfassend:

Empfangen eines Verstärkungs-Codebuchindex;

Schätzen der Verstärkung des festen Beitrags der Anregung im Unterrahmen unter Verwendung eines Parameters, der für eine Klassifizierung des Rahmens repräsentativ ist;

Liefern der quantisierten Verstärkung des adaptiven Beitrags der Anregung und eines Korrekturfaktors aus einem Verstärkungs-Codebuch und für den Unterrahmen in Reaktion auf den Verstärkungs-Codebuchindex;

und
Multiplizieren der geschätzten Verstärkung mit dem Korrekturfaktor, um eine quantisierte Verstärkung des festen Beitrags der Anregung im Unterrahmen bereitzustellen; und

wobei das Schätzen der Verstärkung des festen Beitrags der Anregung für einen ersten Unterrahmen des Rahmens umfasst:

(a) Berechnen einer linearen Schätzung der Verstärkung des festen Beitrags der Anregung im logarithmischen Bereich in Reaktion auf den Parameter, der für die Klassifizierung des Rahmens repräsentativ ist;

(b) Subtrahieren einer Energie eines gefilterten Innovations-Codevektors aus einem festen Codebuch im logarithmischen Bereich von der linearen Verstärkungsschätzung, um eine Verstärkung im logarithmischen Bereich zu erzeugen; und

(c) Umwandeln der Verstärkung im logarithmischen Bereich aus dem Subtrahierer in den linearen Bereich, um die geschätzte Verstärkung zu erzeugen; und

wobei das Schätzen der Verstärkung des festen Beitrags der Anregung das Verwenden des Parameters, der für die Klassifizierung des Rahmens repräsentativ ist, und von Verstärkungen von adaptiven und festen Beiträgen der Anregung mindestens eines vorhergehenden Unterrahmens des Rahmens in jedem Unterrahmen des Rahmens, der dem ersten Unterrahmen folgt, umfasst, um die Verstärkung des festen Beitrags der Anregung zu schätzen.

21. Verfahren zum Abrufen der quantisierten Verstärkungen der adaptiven und festen Beiträge der Anregung nach Anspruch 20, wobei das Verstärkungs-Codebuch Einträge umfasst, die jeder die quantisierte Verstärkung des adaptiven Beitrags der Anregung und den Korrekturfaktor für die geschätzte Verstärkung umfassen.

Revendications

1. Dispositif de quantification d'un gain d'une contribution fixe d'une excitation dans une trame, incluant des sous-trames, d'un signal sonore codé, comprenant :

une entrée pour un paramètre représentatif d'une classification de la trame ;

un estimateur du gain de la contribution fixe de l'excitation dans une sous-trame de ladite trame, à l'aide du paramètre représentatif de la classification de la trame ; et

un quantificateur prédictif du gain de la contribution fixe de l'excitation, dans la sous-trame, à l'aide du gain estimé ;

dans lequel le quantificateur prédictif détermine un facteur de correction pour le gain estimé en tant que quantification du gain de la contribution fixe de l'excitation ;

dans lequel le gain estimé multiplié par le facteur de correction donne le gain quantifié de la contribution fixe de l'excitation ; et

dans lequel l'estimateur comprend, pour une première sous-trame de la trame :

(a) un premier calculateur d'une estimation linéaire du gain de la contribution fixe de l'excitation dans le domaine logarithmique en réponse au paramètre représentatif de la classification de la trame ;

(b) un soustracteur d'une énergie d'un vecteur de code d'innovation filtré issu d'un livre de codes fixe dans le domaine logarithmique, à partir de l'estimation de gain linéaire issue du premier calculateur, le soustracteur produisant un gain dans le domaine logarithmique ;

(c) un convertisseur du gain dans le domaine logarithmique issu du soustracteur vers le domaine linéaire pour produire le gain estimé ; et

(d) un multiplicateur du gain estimé par le facteur de correction pour produire le gain quantifié de la contribution fixe de l'excitation ; et

dans lequel l'estimateur, pour chaque sous-trame de ladite trame suivant la première sous-trame, répond au paramètre représentatif de la classification de la trame et à des gains de contributions adaptative et fixe de l'excitation d'au moins une sous-trame précédente de la trame pour estimer le gain de la contribution fixe de

l'excitation.

2. Dispositif de quantification selon la revendication 1, dans lequel :

5 l'estimateur comprend, pour chaque sous-trame suivant la première sous-trame, un second calculateur d'une estimation linéaire du gain de la contribution fixe de l'excitation dans le domaine logarithmique et un convertisseur de l'estimation linéaire dans le domaine logarithmique vers le domaine linéaire pour produire le gain estimé ; et dans lequel les gains des contributions adaptative et fixe de l'excitation d'au moins une sous-trame précédente de la trame sont des gains quantifiés ; et
 10 les gains quantifiés des contributions adaptatives de l'excitation sont fournis au second calculateur directement, tandis que les gains quantifiés des contributions fixes de l'excitation sont fournis au second calculateur dans le domaine logarithmique au travers d'un calculateur de logarithme.

3. Dispositif de quantification selon la revendication 1 ou 2, dans lequel l'estimateur utilise, pour l'estimation du gain de la contribution fixe de l'excitation, des coefficients d'estimation différents pour chaque sous-trame de la trame.
 15

4. Dispositif de quantification conjointe de gains de contributions adaptative et fixe d'une excitation dans une trame d'un signal sonore codé, comprenant :

20 un quantificateur du gain de la contribution adaptative de l'excitation ; et le dispositif de quantification du gain de la contribution fixe de l'excitation tel que défini selon l'une quelconque des revendications 1 à 3.

5. Dispositif de quantification conjointe des gains des contributions adaptative et fixe de l'excitation selon la revendication 4, comprenant un livre de codes de gain ayant des rubriques comprenant chacune le gain quantifié de la contribution adaptative de l'excitation et un facteur de correction pour le gain estimé.
 25

6. Dispositif de quantification conjointe des gains des contributions adaptative et fixe de l'excitation selon la revendication 5, dans lequel le quantificateur du gain de la contribution adaptative de l'excitation et le quantificateur prédictif du gain de la contribution fixe de l'excitation consultent le livre de codes de gain et sélectionnent le gain de la contribution adaptative de l'excitation à partir d'une rubrique du livre de codes de gain et le facteur de correction de la même rubrique du livre de codes de gain en tant que quantification du gain de la contribution fixe de l'excitation.
 30

7. Dispositif de quantification conjointe des gains des contributions adaptative et fixe de l'excitation selon la revendication 5, comprenant un concepteur du livre de codes de gain pour chaque sous-trame de la trame.
 35

8. Dispositif de quantification conjointe des gains des contributions adaptative et fixe de l'excitation selon la revendication 7, dans lequel le livre de codes de gain possède différentes tailles dans différentes sous-trames de la trame.

9. Dispositif de récupération d'un gain quantifié d'une contribution fixe d'une excitation dans une sous-trame d'une trame, comprenant :
 40

un récepteur d'un indice de livre de codes de gain ;
 un estimateur du gain de la contribution fixe de l'excitation dans la sous- trame, à l'aide d'un paramètre représentatif d'une classification de la trame ;
 45 un livre de codes de gain pour fournir un facteur de correction en réponse à l'indice de livre de codes de gain ; et un multiplicateur du gain estimé par le facteur de correction pour fournir un gain quantifié de la contribution fixe de l'excitation dans ladite sous-trame ;
 dans lequel l'estimateur comprend, pour une première sous-trame de la trame :

- (a) un calculateur d'une estimation linéaire du gain de la contribution fixe de l'excitation dans le domaine logarithmique en réponse au paramètre représentatif de la classification de la trame ;
 - (b) un soustracteur d'une énergie d'un vecteur de code d'innovation filtré issu d'un livre de codes fixe dans le domaine logarithmique, à partir de l'estimation de gain linéaire issue du calculateur, le soustracteur produisant un gain dans le domaine logarithmique ; et
 - (c) un convertisseur du gain dans le domaine logarithmique issu du soustracteur vers le domaine linéaire pour produire le gain estimé ; et
- 50
 55

dans lequel l'estimateur, pour chaque sous-trame de ladite trame suivant la première sous-trame, répond au paramètre représentatif de la classification de la trame et à des gains de contributions adaptative et fixe de l'excitation d'au moins une sous-trame précédente de la trame pour estimer le gain de la contribution fixe de l'excitation.

5

10. Dispositif de récupération de gains quantifiés de contributions adaptative et fixe d'une excitation dans une sous-trame d'une trame, comprenant :

10

un récepteur d'un indice de livre de codes de gain ;
 un estimateur du gain de la contribution fixe de l'excitation dans la sous- trame, à l'aide d'un paramètre représentatif d'une classification de la trame ;
 un livre de codes de gain pour fournir le gain quantifié de la contribution adaptative de l'excitation et un facteur de correction pour la sous-trame en réponse à l'indice de livre de codes de gain ; et
 un multiplicateur du gain estimé par le facteur de correction pour fournir un gain quantifié de la contribution fixe de l'excitation dans la sous-trame ;
 dans lequel l'estimateur comprend, pour une première sous-trame de la trame :

15

20

- (a) un calculateur d'une estimation linéaire du gain de la contribution fixe de l'excitation dans le domaine logarithmique en réponse au paramètre représentatif de la classification de la trame ;
- (b) un soustracteur d'une énergie d'un vecteur de code d'innovation filtré issu d'un livre de codes fixe dans le domaine logarithmique, à partir de l'estimation de gain linéaire issue du calculateur, le soustracteur produisant un gain dans le domaine logarithmique ; et
- (c) un convertisseur du gain dans le domaine logarithmique issu du soustracteur vers le domaine linéaire pour produire le gain estimé ; et

25

dans lequel l'estimateur, pour chaque sous-trame de ladite trame suivant la première sous-trame, répond au paramètre représentatif de la classification de la trame et à des gains de contributions adaptative et fixe de l'excitation d'au moins une sous-trame précédente de la trame pour estimer le gain de la contribution fixe de l'excitation.

30

11. Dispositif de récupération des gains quantifiés des contributions adaptative et fixe de l'excitation selon la revendication 10, dans lequel le livre de codes de gain comprend des rubriques comprenant chacune le gain quantifié de la contribution adaptative de l'excitation et le facteur de correction pour le gain estimé.

35

12. Procédé de quantification d'un gain d'une contribution fixe d'une excitation dans une trame, incluant des sous-trames, d'un signal sonore codé, comprenant :

40

la réception d'un paramètre représentatif d'une classification de la trame ;
 l'estimation du gain de la contribution fixe de l'excitation dans une sous-trame de ladite trame, à l'aide du paramètre représentatif de la classification de la trame ; et
 la quantification prédictive du gain de la contribution fixe de l'excitation, dans la sous-trame, à l'aide du gain estimé ;
 dans lequel la quantification prédictive du gain de la contribution fixe de l'excitation comprend la détermination d'un facteur de correction pour le gain estimé en tant que quantification du gain de la contribution fixe de l'excitation ;
 dans lequel le gain estimé multiplié par le facteur de correction donne le gain quantifié de la contribution fixe de l'excitation ; et
 dans lequel l'estimation du gain de la contribution fixe de l'excitation comprend, pour une première sous-trame de la trame :

50

55

- (a) le calcul d'une estimation linéaire du gain de la contribution fixe de l'excitation dans le domaine logarithmique en réponse au paramètre représentatif de la classification de la trame ;
- (b) la soustraction d'une énergie d'un vecteur de code d'innovation filtré issu d'un livre de codes fixe dans le domaine logarithmique, à partir de l'estimation de gain linéaire pour produire un gain dans le domaine logarithmique ;
- (c) la conversion du gain dans le domaine logarithmique issu de la soustraction vers le domaine linéaire pour produire le gain estimé ; et
- (d) la multiplication du gain estimé par le facteur de correction pour produire le gain quantifié de la contribution

fixe de l'excitation ; et

dans lequel l'estimation du gain de la contribution fixe de l'excitation, pour chaque sous-trame de ladite trame suivant la première sous-trame, répond au paramètre représentatif de la classification de la trame et à des gains de contributions adaptative et fixe de l'excitation d'au moins une sous-trame précédente de la trame pour estimer le gain de la contribution fixe de l'excitation.

13. Procédé de quantification selon la revendication 12, dans lequel l'estimation du gain de la contribution fixe de l'excitation comprend, pour chaque sous-trame suivant la première sous-trame, le calcul d'une estimation linéaire du gain de la contribution fixe de l'excitation dans le domaine logarithmique et la conversion de l'estimation linéaire dans le domaine logarithmique vers le domaine linéaire pour produire le gain estimé, et dans lequel les gains des contributions adaptatives de l'excitation d'au moins une sous-trame précédente de la trame sont des gains quantifiés et les gains des contributions fixes de l'excitation d'au moins une sous-trame précédente de la trame sont des gains quantifiés dans le domaine logarithmique.

14. Procédé de quantification selon la revendication 12 ou 13, dans lequel l'estimation du gain de la contribution fixe de l'excitation comprend l'utilisation, pour l'estimation du gain de la contribution fixe de l'excitation, des coefficients d'estimation différents pour chaque sous-trame de la trame.

15. Procédé de quantification conjointe de gains de contributions adaptative et fixe d'une excitation dans une trame d'un signal sonore codé, comprenant :

la quantification du gain de la contribution adaptative de l'excitation ; et
la quantification du gain de la contribution fixe de l'excitation à l'aide du procédé tel que défini selon l'une quelconque des revendications 12 à 14.

16. Procédé de quantification conjointe des gains des contributions adaptative et fixe de l'excitation selon la revendication 15, à l'aide d'un livre de codes de gain ayant des rubriques comprenant chacune le gain quantifié de la contribution adaptative de l'excitation et un facteur de correction pour le gain estimé.

17. Procédé de quantification conjointe des gains des contributions adaptative et fixe de l'excitation selon la revendication 16, dans lequel la quantification du gain de la contribution adaptative de l'excitation et la quantification du gain de la contribution fixe de l'excitation comprennent la consultation du livre de codes de gain et la sélection du gain de la contribution adaptative de l'excitation à partir d'une rubrique du livre de codes de gain et du facteur de correction de la même rubrique du livre de codes de gain en tant que quantification du gain de la contribution fixe de l'excitation.

18. Procédé de récupération d'un gain quantifié d'une contribution fixe d'une excitation dans une sous-trame d'une trame, comprenant :

la réception d'un indice de livre de codes de gain ;
l'estimation du gain de la contribution fixe de l'excitation dans la sous-trame, à l'aide d'un paramètre représentatif d'une classification de la trame ;
la fourniture, à partir d'un livre de codes de gain et pour la sous-trame, d'un facteur de correction en réponse à l'indice de livre de codes de gain ; et
la multiplication du gain estimé par le facteur de correction pour fournir un gain quantifié de la contribution fixe de l'excitation dans ladite sous-trame ; et
dans lequel l'estimation du gain de la contribution fixe de l'excitation comprend, pour une première sous-trame de la trame :

- (a) le calcul d'une estimation linéaire du gain de la contribution fixe de l'excitation dans le domaine logarithmique en réponse au paramètre représentatif de la classification de la trame ;
- (b) la soustraction d'une énergie d'un vecteur de code d'innovation filtré issu d'un livre de codes fixe dans le domaine logarithmique à partir de l'estimation de gain linéaire pour produire un gain dans le domaine logarithmique ; et
- (c) la conversion du gain dans le domaine logarithmique issu de la soustraction vers le domaine linéaire pour produire le gain estimé ; et

dans lequel l'estimation du gain de la contribution fixe de l'excitation comprend l'utilisation, dans chaque sous-

trame de ladite trame suivant la première sous-trame, du paramètre représentatif de la classification de la trame et de gains de contributions adaptative et fixe de l'excitation d'au moins une sous-trame précédente de la trame pour estimer le gain de la contribution fixe de l'excitation.

5 **19.** Procédé de récupération du gain quantifié de la contribution fixe de l'excitation selon la revendication 18, dans lequel l'estimation du gain de la contribution fixe de l'excitation comprend l'utilisation de coefficients d'estimation différents pour chaque sous-trame de la trame.

10 **20.** Procédé de récupération de gains quantifiés de contributions adaptative et fixe d'une excitation dans une sous-trame d'une trame, comprenant :

la réception d'un indice de livre de codes de gain ;
l'estimation du gain de la contribution fixe de l'excitation dans la sous-trame, à l'aide d'un paramètre représentatif d'une classification de la trame ;

15 la fourniture, à partir d'un livre de codes de gain et pour la sous-trame, du gain quantifié de la contribution adaptative de l'excitation et d'un facteur de correction en réponse à l'indice de livre de codes de gain ; et la multiplication du gain estimé par le facteur de correction pour fournir un gain quantifié de la contribution fixe de l'excitation dans ladite sous-trame ; et

20 dans lequel l'estimation du gain de la contribution fixe de l'excitation comprend, pour une première sous-trame de la trame :

(a) le calcul d'une estimation linéaire du gain de la contribution fixe de l'excitation dans le domaine logarithmique en réponse au paramètre représentatif de la classification de la trame ;

25 (b) la soustraction d'une énergie d'un vecteur de code d'innovation filtré issu d'un livre de codes fixe dans le domaine logarithmique à partir de l'estimation de gain linéaire pour produire un gain dans le domaine logarithmique ; et

(c) la conversion du gain dans le domaine logarithmique issu de la soustraction vers le domaine linéaire pour produire le gain estimé ; et

30 dans lequel l'estimation du gain de la contribution fixe de l'excitation comprend l'utilisation, dans chaque sous-trame de ladite trame suivant la première sous-trame, du paramètre représentatif de la classification de la trame et de gains de contributions adaptative et fixe de l'excitation d'au moins une sous-trame précédente de la trame pour estimer le gain de la contribution fixe de l'excitation.

35 **21.** Procédé de récupération des gains quantifiés des contributions adaptative et fixe de l'excitation selon la revendication 20, dans lequel le livre de codes de gain comprend des rubriques comprenant chacune le gain quantifié de la contribution adaptative de l'excitation et le facteur de correction pour le gain estimé.
